- 1. Motivation
- 2. Estimation and likelihood
- 3. Liability valuation
- 4. Valuation uncertainty
- 5. Conclusions

## 1 Motivation

Q1 What is the uncertainty over a mortality model?Q2 How does this feed into uncertainty over the liabilities?

## 2 Estimation and likelihood

- Specify a statistical model with parameter  $\boldsymbol{\theta}$ .
- Form the log-likelihood function,  $\ell(\boldsymbol{\theta})$ .
- Find  $\hat{\boldsymbol{\theta}}$  which maximises  $\ell(\boldsymbol{\theta})$ .
- $\hat{\boldsymbol{\theta}}$  is the maximum-likelihood estimate (MLE) of unknown true value  $\boldsymbol{\theta}^*$ .

### $\hat{\theta}$ is the Estimate column on the **Model** tab:

#### Model Overview

#### **Model Parameters**

<b>Parameter</b>	Estimate	<b>?</b> Standard error	Z-value	<b>?</b> Pr(> z )	?Sig.	Lives	Oecrements

## 2 Maximum likelihood theorem longevitas

- $\hat{\boldsymbol{\theta}}$  has multivariate normal distribution (MVN)<sup>†</sup>.
- This holds irrespective of the model structure. *θ̂* ~ MVN(*θ*<sup>\*</sup>, Σ<sup>\*</sup>).
- $\theta^*$  and  $\Sigma^*$  unknown, so use  $\hat{\theta}$  and  $\hat{\Sigma}$ .
- $\hat{\theta}$  and  $\hat{\Sigma}$  both estimated from log-likelihood.

### <sup> $\dagger$ </sup> Cox and Hinkley [1996, Chapter 9(iii)].

### $\hat{\Sigma}$ is the covariance matrix on the **Covariances** tab:

Serivatives

## 4 Valuation uncertainty

- $\hat{\theta}$  is uncertain.
- So reserve,  $V(\hat{\theta})$ , is also uncertain.
- Use delta method to approximate variance of reserve.

*θ̂* is a random variable, i.e. *θ̂* ~ MVN(*θ̂*, *Σ̂*).
Reserve, V(*θ̂*), is a function of a random variable.
Var[V(*θ̂*)] ≈ *a<sup>T</sup>Σ̂a*, where *a* = ∂V(*θ̂*)/∂*θ*|<sub>*θ*=*θ̂*</sub>

### $\boldsymbol{a}$ for males, females and combined:

#### Derivatives

Below are the first partial derivatives of the liability values with respect to the various parameters, i.e. the sensitivities of the liability values to change in each parameter value. These are used in conjunction with the parameter covariance matrix to approximate the variances of the liability values using the delta method, and thus obtain the standard errors of the liability values shown in the table above.

With respect to:	Males	Females	Combined

## 5 Conclusions

- Maximum-likelihood estimation produces  $\hat{\theta}$  and  $\hat{\Sigma}$ .
- Estimate of reserves using  $\hat{\theta}$ .
- Estimate variance of reserves using delta method.
- Implicit assumption of normal distribution for reserve valuation.

- D. R. Cox and D. V. Hinkley. *Theoretical Statistics*. Chapman and Hall, 1996. ISBN 0-412-16160-5.

## Mis-estimation for pricing

Stephen J. Richards 26th January 2023

Copyright © Longevitas Ltd. All rights reserved. This presentation may be freely distributed, provided it is unaltered and has this copyright notice intact.

- 1. Motivation
- 2. Recap
- 3. Reserve distribution
- 4. Delta method v. sampling
- 5. Conclusions

### This presentation is about how to use the mis-estimation features in the Longevitas survival-modelling software.

For the theory and technical details, see .www.longevitas.co.uk/mis-estimation-risk

## 1 Motivation

# What is the true distribution of reserve values in response to parameter uncertainty?

- *θ̂* is the maximum-likelihood estimate (MLE). *θ̂* has approximate MVN(*θ̂*, *Σ̂*) distribution.
- Reserve,  $V(\hat{\theta})$ , is thus also a random variable.
- Approximate variance of  $V(\hat{\theta})$  using delta method.

### However:

- Using delta method assumes that  $V(\hat{\theta})$  is normally distributed.
- In practice  $V(\hat{\theta})$  is not necessarily normally distributed.
- Want to know the true distribution of  $V(\hat{\theta})$ , especially if not symmetric.

Sampling approach from Richards [2016]:

- 1. Sample  $\boldsymbol{\theta}_j$  from MVN $(\boldsymbol{\hat{\theta}}, \boldsymbol{\hat{\Sigma}})$ .
- 2. Calculate  $V(\boldsymbol{\theta}_j)$ .
- 3. Repeat steps 1 and 2 for  $j = 1, 2, \ldots, nsamp$ .
- 4. Resulting set of nsamp values represents sample from true distribution of  $V(\hat{\theta})$ .

## 4 Sampling approach

## MalesFemalesReserve ( $\pounds$ m)2,6692,290Standard error ( $\pounds$ m)17.49.9

## Males Females Reserve 100.00% 99.99% Standard error 100.61% 99.80%

## 5 Conclusions

- In this particular case, the delta method was a highly accurate approximation.
- This may not be true of all models and data sets.
- Use either delta method or sampling mis-estimation to understand response of reserve estimate to parameter uncertainty.

# S. J. Richards. Mis-estimation risk: measurement and impact. British Actuarial Journal, 21 (3):429–457, 2016. doi: 10.1017/S1357321716000040.

### Mis-estimation: value-at-risk

Stephen J. Richards 26th January 2023

Copyright © Longevitas Ltd. All rights reserved. This presentation may be freely distributed, provided it is unaltered and has this copyright notice intact.

- 1. Motivation
- 2. Pricing view v. value-at-risk
- 3. Simulation
- 4. Conclusions

### This presentation is about how to use the mis-estimation features in the Longevitas survival-modelling software.

For the theory and technical details, see .www.longevitas.co.uk/mis-estimation-risk

## 1 Motivation

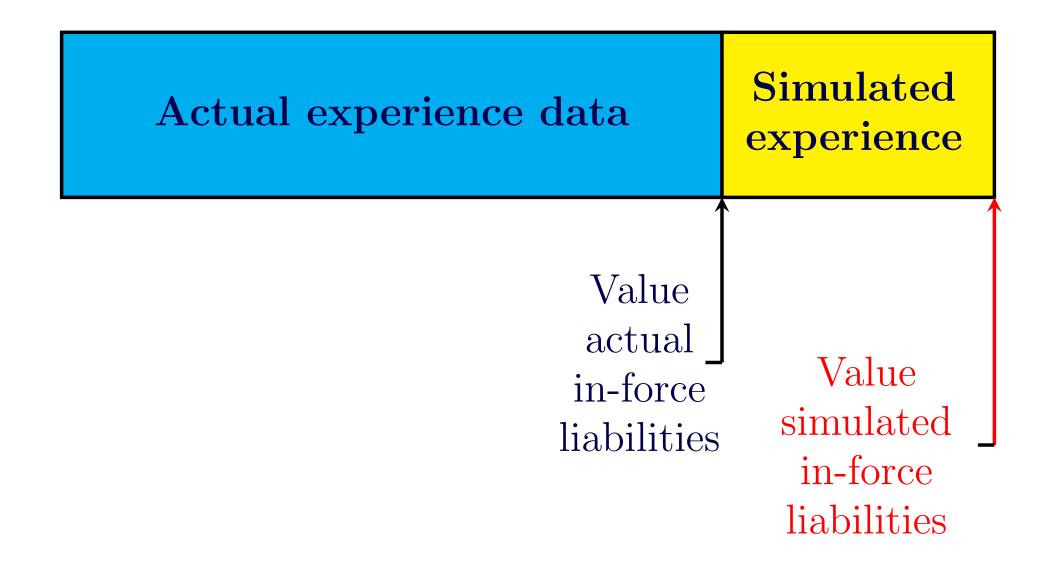

## 1 Mis-estimation: value-at-risk Congevitas

Q1 How sensitive is the mortality model to new data?
Q2 How sensitive is the reserve to model recalibration?
Q3 What capital is needed to cover recalibration risk?

## 2 Pricing view v. value-at-risk **Congevitas**

Q. Why value liabilities at end of simulation period?
A. To simultaneously measure mis-estimation risk and idiosyncratic risk; see Richards [2021, Table 9].

## 2 VaR mis-estimation

#### Switch on VaR mis-estimation by selecting horizon:

	· · ·			No VaR	^
		<b>D</b> Modelling		One year	
Application	Deduplication		<b>X</b> Rating	Two years	
				Three years	
Calculation	n Core			Four Years	
				Five years	
Model Ana	alysis Defaults			Six years	
2 Porform Por	atotran Analysia			Seven years	
	otstrap Analysis			Eight years	
🕐 Bootstrap S	ample Size			Nine years	
🙁 Bootstrap S	imulation Count			Ten years	þ
🛿 Bootstrap Ir	herit Sizebands			Fifteen years	
🛛 Run-off Sim	ulation Count			Twenty years	~)
🛛 🕄 Mis-estimati	ion VaR Horizon			No VaR	~
[ ] Mis-estimati	ion VaR Parameter Ris	k		Yes	~
<table-cell> Mis-estimati</table-cell>	on VaR Idiosyncratic	Risk		No	~
🙎 Mis-estimati	ion VaR Output			Yes	~
🙁 Liability Val	uation			Yes plus first-derivatives	~
2 Valuation M	ortality Level			Static as per rate-table start year	~
🛛 Geographic				All records in model	<b>v</b>
w.longevitas.co	.uk urves Tooltips Bevond	I		Alwavs display tooltips	<b>~</b> 9/

#### Switch between actual in-force and simulated in-force:

Application Ceduplication Modellin	g Kating Projections	
Solution Core		
Model Analysis Defaults		*
Defense De statem Analysis		
Perform Bootstrap Analysis	No	~
🕄 Bootstrap Sample Size	10 thousand	~
Bootstrap Simulation Count	1000	~
Bootstrap Inherit Sizebands	Yes	~
Run-off Simulation Count	No run-off simulations	~
Mis-estimation VaR Horizon	No VaR	~
Mis-estimation VaR Parameter Risk	Yes	~
Mis-estimation VaR Idiosyncratic Risk	No	~
Mis-estimation VaR Output	Yes	~

#### Switch on output of simulated deaths and time lived:

Application	<b>D</b> Modelling	<b>X</b> Rating	□< Projections	
Selection Core				
Model Analysis Defaults				*
Perform Bootstrap Analysis			No	<b>v</b>
Bootstrap Sample Size			10 thousand	V
Bootstrap Simulation Count			1000	~
Bootstrap Inherit Sizebands			Yes	~
Run-off Simulation Count			No run-off simulations	~
Mis-estimation VaR Horizon			No VaR	~
Mis-estimation VaR Parameter Ris	k		Yes	~
Mis-estimation VaR Idiosyncratic F	Risk		No	~
Mis-estimation VaR Output			Yes	~

## 3 Simulation

*θ̂* is the maximum-likelihood estimate (MLE). *θ̂* has approximate MVN(*θ̂*, *Σ̂*) distribution.

- Two options for simulating n-year experience:
  - 1. Without parameter risk: just use  $\hat{\theta}$ .
  - 2. With parameter risk: sample from  $MVN(\hat{\theta}, \hat{\Sigma})$ .

#### Switch VaR parameter risk on or off in configuration:

Application	<b>D</b> Modelling	* Rating	D ← Projections	
Selection Core				
Model Analysis Defaults				*
			(	
Perform Bootstrap Analysis			No	~
Bootstrap Sample Size			10 thousand	~
Bootstrap Simulation Count			1000	~
Bootstrap Inherit Sizebands			Yes	~
Run-off Simulation Count			No run-off simulations	~
Mis-estimation VaR Horizon			No VaR	~
[2] Mis-estimation VaR Parameter Risk			Yes	~
Mis-estimation VaR Idiosyncratic Ri	sk		No	~
Mis-estimation VaR Output			Yes	~

## 4 Conclusions

**PONGEVITAS** 

Options for liability estimation risk in Longevitas:

- 1. **Delta method**. For pricing block transactions. Assumes normal distribution for liability value, which might not always be true.
- Richards [2016]. For pricing block transactions. Makes no assumption about distribution of liability value.
- 3. Richards [2021]. Value-at-risk approach for one-year Solvency II reporting, ORSA etc.
